Abstract:

In the second wave of financial crisis, namely the sovereign debt crisis, the country's most affected by this phenomenon are Greece, Italy, Spain, Portugal, Ireland and last year Cyprus joined. Future more the crisis in Greece in 2015 requires local authorities to evaluate constantly their rating in order to prevent bankruptcy. In this paper we conducted a comparative analysis using Altman method and the Stickney method and correlate the scores with ratings agencies Standard & Poor's and Moody's.

Key words: public debt, rating, standing, liquidity, performance

JEL classification: H72

1. LITERATURE REVIEW

The international financial crisis has prompted more than ever rating agencies such as Moody's, Standard & Poor's, Fitch IBCA and Thomson Bank Watch to prepare quarterly reports on the rating of banks, large corporations, municipalities and countries to highlight risk posed to investors. For this process a number of agencies search financial and non-financial information relating to issuers of securities standing in the financial market. Financial information taken from the financial statements, forecasts, investment programs and international news will be the basis of determining the assessed rating after selection and adjustment.

Some authors test the hypothesis that major credit rating agencies (CRAs) have been inconsistent in assessing the implications of monetary union membership for sovereign risks. [1]

Using ordered logit and probit plus random effects ordered probit approaches, in their study other authors established the determinants of sovereign debt ratings. [2]

Other authors' empirical findings indicate that tradeoffs occur between highway project–related debt and other state debt in those states with formal restrictions on total general obligation and revenue backed debt (umbrella debt limits). [3]

In a recent paper authors investigate the impact of state-level tax and expenditure limits (TELs) on state government revenues and aid to local governments. Using an instrumental variable approach to control for endogeneity, the authors find that the general fund TELs (i.e., revenue and expenditure limits) have led to substantial increases in tax and non-tax revenues. [4]

American authors studied the impact of state tax and expenditure limitations (TELs) on bond credit ratings used an incomplete panel in US states in which the authors find limited differences in the fiscal and economic variables that influence the ratings of the two agencies respectively Standard&Poor's and Moody's. [5]

Politicians often propose force strategies in fighting the underground economy in order to increase budget revenues: some advocate for trust-based strategies, some advocate for power-based strategies and others for an appropriate mixture of trust and power [6-10].

Romanian authors explain that the public debt includes all amounts borrowed by government, the administrative units and other public entities, individuals or legal entities from domestic and abroad and of outstanding at a time. [11]

Same authors said that the obligations represent commitments arising from borrowing, i.e. repayment of principal, payment of interest, fees, special benefits granted to creditors. [12]

On the other hand the international financial crisis has prompted more than ever rating agencies such as Moody's, Standard & Poor's, Fitch IBCA and Thomson Bank Watch prepare quarterly reports on the rating of banks, large corporations, municipalities and countries to highlight risk posed to investors.

In our opinion the financial information taken from the financial statements, forecasts, and investment programs will be the basis of determining the rating, which is a measure of the financial standing health of the companies and local public administration.

2. METHOD AND RESULTS

Rating agencies analyze the information needed to assess risks associated with an issue of securities based on the trend registered by the entities in the past five years.

During the time, in evaluation rating process, the rating agencies took into account the three principles:

- certainty ability to pay, at maturity, the interest and to repayment the amounts borrowed;
- nature and the insurance / bond provisioning;

• management decisions to prevent the bankruptcy, such as the reorganization and the financial restructuring, which not could affect the rights of creditors.

2.1. The importance of rating agencies in the financial markets

In Romania each bank has own rating system, to establish the financial standing of the companies and local administration. These ratings are based both on the financial ratios and non-financial information and show the risk associated with losses in the event of defaulting on payment of a debtor and the recovery of these losses.

Most rating systems contain between six and ten different ranks that are sufficient to achieve a classification according to risk classes.

Until now, the market is dominated by three major rating agencies: Standard & Poor's Ratings Group, Moody's Investors Service and Fitch - IBCA and the focus is on assessing credit risk associated with debt in the form of securities / bonds issued by companies, municipalities, banks or countries which are traded on the international market.

Rating agencies products use uppercase and lowercase letters (A, B and C). Thus the "Standard & Poor's" agency notes the rating by uppercase and "Moody's Investor Service" used a combinations of uppercase, lowercase letters and digits.

The rating system applied to individual borrowers varies from agency to agency; some prefer to analyze financial criteria while others are more focused on quality criteria in the risk process evaluation.

Thus the financial criteria involve performance ratios, liquidity and solvency, debts ratios, turnover growth while the nonfinancial information is: industry development, competitive advantage, quality management and shareholders in compliance with required standards.

From our point of view the raking based on financial criteria can be applied as well in the banking industry, financial industry and in local government administration.

In our paper we use the financial analysis ratios in order to assess the financial policy of the county government in Romania in the last period and thus, facilitate the future decisions in local administration.

Therefore we used The Altman Model and the Stickney Model to measure the rating and the probability of bankruptcy of the public administration, and to correlate these ratings with agencies Standard&Poors and Moody's products.

2.2. The Ratings of local government county in Romania

The financial analysis used in local administration is a tool to assess the financial policy of the county government and to facilitate the future public decisions based on the financial statements of county local government.

On the other hand financial analysis takes into account the public activity of county government, the quality of the public management, the administration personnel, motivation and the public performance.

Results of the analysis undertaken by the county government may be intended either for internal users and especially its staff management or external users, bankers or other investors.

In our opinion, the financial analysis should be focused on the main factors used in credit risk evaluation and in the ranking process.

Analysis of the local government rating is based on a number of indicators used in the financial analysis, which takes into account the financial strengths of local government: to issue county bonds, to access bank loans in public debt limits.

Three types of evaluation of the financial issues, namely univariate analysis, multivariate analysis and logit analysis are addressed in financial theory.

Univariate model proposed by William Beaver achieved a moderate level of accuracy of prediction. [13]

The most commonly used model was proposed by Edward Altman, Professor of Finance at the Stern School of Business at New York University.

More recently model used in rating analysis is the Stickney model [14], whose application is based on four stages:

• In the first stage is calculated seven financial ratios according with the data table:

Table 1. The Stienney Would						
Financial ratios	Coefficients					
Constant	+ 0,23883					
Stocks/Turnover	- 0,108					
Receivables/Stocks	- 1,583					
(Cash + Short term investment)/Total Assets	- 10,78					
Current Assets/Current liabilities	+ 3,074					
Operating profit/(Total Assets – Total current debts)	+ 0,486					
Long term liabilities/(Total Assets –Total current debts)	- 4,35					
Turnover/(Working capital + Fixed Assets)	+ 0,11					
y =	Constant + \sum (Coefficient * Financial ratio)					
Probability of bankruptcy =	$1/(1 + e^{y})$					

Table 1. The Stickney Model

Source: C.P. Stickney, *Financial Reporting and Statement Analysis, 3rd Edition*. The Dryden Press, Ft.Worth: TX, 1996

• In the second stage each ratio is multiplied by a coefficient that can take positive or negative values.

- In the third stage partial products are added together.
- Finally default probability is calculated as the inverse function $(1+e^y)$.

Source: own calculations

As we observe starting with 2008 until 2013 the local authorities had a strong rating A-. In 2014 the rating of these authorities' decreases at rating BB as consequences of public debt increased to finance the local projects investments.

A way of correlating with Stickney score with the rating agencies Standard & Poor's and Moody's is shown in the following table:

Risk grade	Bankruptcy probability	Local county government rating				
		Moody's	Standard&Poor's			
1	0,0-0,15	A3	A-			
2	0,15-0.3	Baa1/Baa2	BBB+/BBB			
3	0,3-0,6	Baa2/Baa3	BBB/BBB-			
4	0,6-1,2	Ba1/Ba2	BB+/BB/BB-			
5	1,2-2,5	Ba3	B+/B			
6	2.5-5	B1	B-			
7	5-10	B2/B3	CCC			
8	Over 10	CaaCa/C	CC/C			

 Table 3. The correlation between Stickney Ratings and the Agencies Ratings

Source: Adaptation E. Cade, Managing Banking Risks Woodhead Publishing, 1997, p. 115

Bond ratings are issued by bond rating agencies, the most prominent of which are **Moody's** and **Standard&Poor's.** The ratings attest to the creditworthiness of a firm: The probability that adverse conditions will result in financial difficulties is taken into consideration assessing the like hood of the firm defaulting on its interest or principal payments. Bond indentures and the degree of protection afforded in the event of bankruptcy are among other important considerations in the rating process. [15]

The relation between bond rating and Z-score adjusted for an intercept of 3.25 is the follow:

$Z = 6.56X_1 + 3.26 X_2 + 6.72X_3 + 1.05X_4 + 3.25$

X₁=Working capital/Total Assets -reflects liquidity

X₂= Retained earnings/Total assets-reflects age of firm and cumulative profitability

X₃=Earnings before interest and taxes/Total Assets-reflects profitability

X₄= Shareholder's equity/Total Liabilities-reflects financial structure

Tuble 4: the Intillation	porate Donus Rating

Source: Own calculus

As we observe the Altman ratings are more restrictive comparing with Stickney ratings. Thus 2008 - 2012 the ratings are constant at BB level, while 2013 and 2014 the ratings decreased to B level.

Based on both models we can establish the following relations with Standard&Poor's and Moody's ratings.

	I ubic of II	ie ioeui govei	minent i at		
US Bond	Altman Z-	Stickney	Risk	Moody's	Standard&Poor's
Standard&Poor's Rating	score	Bankruptcy	Grade	Ratings	Ratings
		Probability			
AAA	8.15	-	-	-	-

Table 7. The comparison between Stickney and Altman Models

Source: Own calculus

As we saw the ratings both Altman and Stickney models are very close, which means the Altman model or Stickney model may be used in determining the rating of local governments.

3. CONCLUSIONS

- The rating is an important method in predicting the financial stability of local governments;

- Local governments must periodically evaluate their ratings to increase investors' confidence in their ability to repay loans and interests and the public debts;

- Rating models must reflect the risk of bankruptcy among local governments, based on local financial autonomy;

- Both Altman and Stickney models are important tools for the local authorities in measuring the financial health of its standing.

- We consider that based on this model it is possible to build other important rating models for particular cases in Romanian local administration for measuring its financial health.
